

AI Engineer — Practical Assessment

AI Search Visibility & Recommendation

7 calendar days · Deliverables: source code, README, one sample report, and a 5 minute screen recording.

1. The problem

Boutiquaat wants to understand and improve its visibility in AI-powered search and recommendation systems such as ChatGPT, Perplexity, Google AI Overviews/AI Mode, and similar platforms. A customer who once searched for “best skincare websites” increasingly asks an AI assistant “I want to buy skincare products online. Which companies would you recommend?” instead.

We want to know: when Boutiquaat is relevant to a customer's question, why is it recommended or not recommended by AI systems — and what would have to change for it to be recommended by these chat models like ChatGPT etc.

2. Your task

Build a working Python prototype — frontend and backend — that takes a set of customer questions (“Where can I buy Korean skincare?”, “What are the best beauty shopping websites?”, “What are the best skincare retailers in the Middle East?”) and analyses Boutiquaat's visibility in AI-generated answers: whether Boutiquaat is mentioned, recommended, or absent, how it ranks against competitors, and what sources or content support it. It should also identify why Boutiquaat may not be appearing and what opportunities exist to improve its visibility. Everything is your call — architecture, libraries, LLM provider, how you source or simulate AI answers, how you decide whether Boutiquaat is relevant, what you measure, what you leave out. We are assessing your judgement, not your feature count. A small system that works, is tested, and that you can defend beats a large one that is half-finished; tell us in the README what you deliberately cut and why. A screen recording of the workflow explaining each step.

3. Ground rules

Identify what you used. AI coding assistants are allowed — but we will ask you to walk through your choices and the alternatives you rejected, so submit only what you can defend.

4. How we evaluate

The reasoning behind your methodology and evaluation approach, followed by code quality and AI/LLM implementation, architecture, then testing, documentation, and how clearly you explain the work.
